1.7 Matrices

Contents

- * 1.7.1 Introduction to Matrices
- * 1.7.2 Operations with Matrices
- * 1.7.3 Determinants & Inverses
- * 1.7.4 Solving Systems of Linear Equations with Matrices

1.7.1 Introduction to Matrices

Your notes

Introduction to Matrices

Matrices are a useful way to represent and manipulate data in order to model situations. The elements in a matrix can represent data, equations or systems and have many real-life applications.

What are matrices?

- A matrix is a rectangular array of elements (numerical or algebraic) that are arranged in rows and
- The **order** of a matrix is defined by the **number** of rows and columns that it has
 - The order of a matrix with m rows and n columns is $m \times n$
- A matrix \boldsymbol{A} can be defined by $\boldsymbol{A}=(a_{ij})$ where i=1,2,3,...,m and j=1,2,3,...,n and a_{ij} refers to the element in row i, column j

Number of columns, n = 3

$$A = (a_{i,j}) = \begin{pmatrix} a_{1,1} & a_{1,2} & a_{1,3} \\ a_{2,1} & a_{2,2} & a_{2,3} \end{pmatrix}$$
 Number of rows, $m = 2$

What type of matrices are there?

- A **column matrix** (or column vector) is a matrix with a **single column**, n = 1
- A row matrix is a matrix with a single row, m = 1
- A square matrix is one in which the number of rows is equal to the number of columns, m = n
- Two matrices are equal when they are of the same order and their corresponding elements are equal,
 i.e. a_{ii} = b_{ii} for all elements
- A zero matrix, \mathbf{O} , is a matrix in which all the elements are 0, e.g. $\mathbf{O} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$
- The identity matrix, \boldsymbol{I} , is a **square** matrix in which all elements along the **leading diagonal** are 1 and the rest are 0, e.g. $\boldsymbol{I} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$

Examiner Tip

Make sure that you know how to enter and store a matrix on your GDC

Let the matrix $\mathbf{A} = \begin{pmatrix} 5 & -3 & 7 \\ -1 & 2 & 4 \end{pmatrix}$

a) Write down the order of \boldsymbol{A} .

b) State the value of $a_{2,3}$.

1.7.2 Operations with Matrices

Your notes

Matrix Addition & Subtraction

Just as with ordinary numbers, **matrices** can be **added** together and **subtracted** from one another, provided that they meet certain conditions.

How is addition and subtraction performed with matrices?

- Two matrices of the **same order** can be added or subtracted
- Only corresponding elements of the two matrices are added or subtracted

•
$$\mathbf{A} \pm \mathbf{B} = (a_{ij}) \pm (b_{ij}) = (a_{ij} \pm b_{ij})$$

• The **resultant** matrix is of the **same order** as the original matrices being added or subtracted

What are the properties of matrix addition and subtraction?

- A + B = B + A(commutative)
- A + (B + C) = (A + B) + C (associative)
- A+O=A
- O-A=-A
- A B = A + (-B)

Examiner Tip

• Make sure that you know how to add and subtract matrices on your GDC for speed or for checking work in an exam!

Consider the matrices $\mathbf{A} = \begin{pmatrix} -4 & 2 \\ 7 & 3 \\ 1 & -5 \end{pmatrix}, \mathbf{B} = \begin{pmatrix} 2 & 6 \\ 5 & -9 \\ -2 & -3 \end{pmatrix}.$

$$A + B = \begin{pmatrix} -4 & 2 \\ 7 & 3 \\ 1 & -5 \end{pmatrix} + \begin{pmatrix} 2 & 6 \\ 5 & -9 \\ -2 & -3 \end{pmatrix} = \begin{pmatrix} -2 & 8 \\ 12 & -6 \\ -1 & -8 \end{pmatrix}$$

b) Find $\boldsymbol{A} - \boldsymbol{B}$.

$$A - G = \begin{pmatrix} -4 & 2 \\ 7 & 3 \\ 1 & -5 \end{pmatrix} - \begin{pmatrix} 2 & 6 \\ 5 & -9 \\ -2 & -3 \end{pmatrix} = \begin{pmatrix} -6 & -4 \\ 2 & 12 \\ 3 & -2 \end{pmatrix}$$

Matrix Multiplication

Matrices can also be multiplied either by a scalar or by another matrix.

How do I multiply a matrix by a scalar?

- Multiply each element in the matrix by the scalar value
 - $k\mathbf{A} = (ka_{ii})$
- The **resultant** matrix is of the **same order** as the original matrix
- Multiplication by a negative scalar changes the sign of each element in the matrix

How do I multiply a matrix by another matrix?

- To multiply a matrix by another matrix, the number of columns in the first matrix must be equal to the number of rows in the second matrix
- If the order of the **first** matrix is $m \times n$ and the order of the **second** matrix is $n \times p$, then the order of the **resultant** matrix will be $m \times p$
- The product of two matrices is found by multiplying the corresponding elements in the row of the first matrix with the corresponding elements in the column of the second matrix and finding the sum to place in the resultant matrix

■ E.g. If
$$\mathbf{A} = \begin{bmatrix} a & b & c \\ d & e & f \end{bmatrix}$$
, $\mathbf{B} = \begin{bmatrix} g & h \\ i & j \\ k & l \end{bmatrix}$

■ then $\mathbf{A}\mathbf{B} = \begin{bmatrix} (ag + bi + ck) & (ah + bj + cl) \\ (dg + ei + fk) & (dh + ej + fl) \end{bmatrix}$

■ then $\mathbf{B}\mathbf{A} = \begin{bmatrix} (ga + hd) & (gb + he) & (gc + hf) \\ (ia + jd) & (ib + je) & (ic + jf) \\ (ka + ld) & (kb + le) & (kc + lf) \end{bmatrix}$

How do I square an expression involving matrices?

- If an expression involving matrices is squared then you are multiplying the expression by itself, so write it out in bracket form first, e.g. $(A + B)^2 = (A + B)(A + B)$
 - remember, the regular rules of algebra do not apply here and you cannot expand these brackets, instead, add together the matrices inside the brackets and then multiply the matrices together

What are the properties of matrix multiplication?

- $AB \neq BA$ (non-commutative)
- A(BC) = (AB)C (associative)
- A(B+C) = AB + AC (distributive)
- (A+B)C = AC + BC (distributive)
- $\bullet AI = IA = A \text{ (identity law)}$

- AO = OA = O, where O is a zero matrix
- Powers of square matrices: $A^2 = AA$, $A^3 = AAA$ etc.

Examiner Tip

 Make sure that you are clear on the properties of matrix algebra and show each step of your calculations

Your notes

Consider the matrices
$$\mathbf{A} = \begin{bmatrix} 4 & 2 & -5 \\ -3 & 8 & 1 \\ -1 & -2 & 2 \end{bmatrix}$$
 and $\mathbf{B} = \begin{bmatrix} 5 & 1 \\ -2 & 5 \\ 9 & 7 \end{bmatrix}$.

a) Find \boldsymbol{AB} .

$$AB = \begin{pmatrix} 4 & 2 & -5 \\ -3 & 8 & 1 \\ -1 & -2 & 2 \end{pmatrix} \times \begin{pmatrix} 5 & 1 \\ -2 & 5 \\ 9 & 7 \end{pmatrix}$$

$$= \begin{pmatrix} (4 \times 5 + 2 \times -2 + -5 \times 9) & (4 \times 1 + 2 \times 5 + -5 \times 7) \\ (-3 \times 5 + 8 \times -2 + 1 \times 9) & (-3 \times 1 + 8 \times 5 + 1 \times 7) \\ (-1 \times 5 + -2 \times -2 + 2 \times 9) & (-1 \times 1 + -2 \times 5 + 2 \times 7) \end{pmatrix}$$

$$= \begin{pmatrix} (20 - 4 - 45) & (4 + 10 - 35) \\ (-15 - 16 + 9) & (-3 + 40 + 7) \\ (-5 + 4 + 18) & (-1 - 10 + 14) \end{pmatrix}$$

$$AB = \begin{pmatrix} -29 & -21 \\ -22 & 44 \\ 17 & 3 \end{pmatrix}$$

b) Explain why you cannot find ${m B}{m A}$.

BA cannot be found because the number of columns in B is different to the number of rows in A

c) Find A^2 .

$$A^{2} = \begin{pmatrix} 4 & 2 & -5 \\ -3 & 8 & 1 \\ -1 & -2 & 2 \end{pmatrix}^{2} = \begin{pmatrix} 4 & 2 & -5 \\ -3 & 8 & 1 \\ -1 & -2 & 2 \end{pmatrix} \begin{pmatrix} 4 & 2 & -5 \\ -3 & 8 & 1 \\ -1 & -2 & 2 \end{pmatrix}$$

$$= \begin{pmatrix} (4 \times 4 + 2 \times -3 + -5 \times -1) & (4 \times 2 + 2 \times 8 + -5 \times -2) & (4 \times -5 + 2 \times 1 + -5 \times 2) \\ (-3 \times 4 + 8 \times -3 + 1 \times -1) & (-3 \times 2 + 8 \times 8 + 1 \times -2) & (-3 \times -5 + 8 \times 1 + 1 \times 2) \\ (-1 \times 4 + -2 \times -3 + 2 \times -1) & (-1 \times 2 + -2 \times 8 + 2 \times -2) & (-1 \times -5 + -2 \times 1 + 2 \times 2) \end{pmatrix}$$

$$A^{2} = \begin{pmatrix} 15 & 34 & -28 \\ -37 & 56 & 25 \\ 0 & -22 & 7 \end{pmatrix}$$

1.7.3 Determinants & Inverses

Your notes

Determinants

What is a determinant?

- The **determinant** is a **numerical value** (positive or negative) calculated from the elements in a matrix and is used to find the **inverse** of a matrix
- You can only find the determinant of a **square** matrix
- The method for finding the determinant of a 2×2 matrix is given in your **formula booklet**:

$$\mathbf{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \Rightarrow \det \mathbf{A} = |\mathbf{A}| = ad - bc$$

- You only need to be able to find the determinant of a 2×2 matrix by hand
 - For larger $n \times n$ matrices you are expected to use your GDC
- The determinant of an identity matrix is $\det(\mathbf{I}) = 1$
- The determinant of a zero matrix is $\det(O) = 0$
- When finding the determinant of a **multiple** of a matrix or the **product** of two matrices:
 - $\det(k\mathbf{A}) = k^2 \det(\mathbf{A})$ (for a 2×2 matrix)
 - $= \det(\mathbf{A}\mathbf{B}) = \det(\mathbf{A}) \times \det(\mathbf{B})$

Consider the matrix $\mathbf{A} = \begin{pmatrix} 3 & -6 \\ p & 7 \end{pmatrix}$, where $p \in \mathbb{R}$ is a constant.

Determinant of a 2×2
$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \Rightarrow \det A = |A| = ad - bc$$

So,
$$-3 = 21 + 6\rho$$

 $-24 = 6\rho$

b) Find the determinant of $4\boldsymbol{A}$.

$$det(4A) = 4^2 \times -3 = -48$$

Head to www.savemyexams.com for more awesome resources

Inverse Matrices

How do I find the inverse of a matrix?

- The determinant can be used to find out if a matrix is invertible or not:
 - If $\det \mathbf{A} \neq 0$, then \mathbf{A} is invertible
 - If $\det A = 0$, then A is singular and does **not** have an inverse
- The method for finding the inverse of a 2×2 matrix is given in your **formula booklet**:

$$\mathbf{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \Rightarrow \mathbf{A}^{-1} = \frac{1}{\det \mathbf{A}} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}, ad \neq bc$$

- You only need to be able to find the inverse of a 2×2 matrix by hand
 - For larger $n \times n$ matrices you are expected to use your GDC
- The inverse of a square matrix A is the matrix A^{-1} such that the product of these matrices is an identity matrix. $AA^{-1} = A^{-1}A = I$
 - As a result of this property:
 - $AB = C \Rightarrow B = A^{-1}C$ (pre-multiplying by A^{-1})
 - $BA = C \Rightarrow B = CA^{-1}$ (post-multiplying by A^{-1})

SaveMyExams

Head to www.savemyexams.com for more awesome resources

Worked example

Consider the matrices $\mathbf{P} = \begin{pmatrix} 4 & -2 \\ 8 & 2 \end{pmatrix}$, $\mathbf{Q} = \begin{pmatrix} k & 6 \\ -5 & 3 \end{pmatrix}$ and $\mathbf{R} = \begin{pmatrix} 18 & 18 \\ 6 & 54 \end{pmatrix}$, where k is a constant.

a) Find P^{-1} .

Determinant of a
$$2 \times 2$$

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \Rightarrow \det A = |A| = ad - bc$$

Inverse of a 2×2 matrix
$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \Rightarrow A^{-1} = \frac{1}{\det A} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}, ad \neq bc$$

$$\rho^{-1} = \frac{1}{4 \times 2 - (-2) \times 8} \begin{pmatrix} 2 & 2 \\ -8 & 4 \end{pmatrix}$$

$$= \frac{1}{24} \begin{pmatrix} 2 & 2 \\ -8 & 4 \end{pmatrix}$$

$$\rho^{-1} = \begin{pmatrix} \frac{1}{12} & \frac{1}{12} \\ -\frac{1}{3} & \frac{1}{6} \end{pmatrix}$$

b) Given that PQ = R find the value of k.

$$\begin{pmatrix} k & 6 \\ -5 & 3 \end{pmatrix} = \begin{pmatrix} \frac{1}{12} & \frac{1}{12} \\ -\frac{1}{3} & \frac{1}{6} \end{pmatrix} \begin{pmatrix} 18 & 18 \\ 6 & 54 \end{pmatrix}$$

$$\begin{pmatrix} k & 6 \\ -5 & 3 \end{pmatrix} = \begin{pmatrix} \left(\frac{1}{12} \times 18 + \frac{1}{12} \times 6\right) & \left(\frac{1}{12} \times 18 + \frac{1}{12} \times 54\right) \\ \left(-\frac{1}{12} \times 18 + \frac{1}{6} \times 6\right) & \left(-\frac{1}{3} \times 18 + \frac{1}{6} \times 54\right) \end{pmatrix}$$

$$\begin{pmatrix} k & 6 \\ -5 & 3 \end{pmatrix} = \begin{pmatrix} 2 & 6 \\ -5 & 3 \end{pmatrix}$$

1.7.4 Solving Systems of Linear Equations with Matrices

Your notes

Solving Systems of Linear Equations with Matrices

Matrices are used in a huge variety of applications within engineering, computing and business. They are particularly useful for encrypting data and forecasting from given data. Using matrices allows for much larger and more complex systems of linear equations to be solved easily.

How do you set up a system of linear equations using matrices?

- A linear equation can be written in the form Ax = b, where A is the matrix of **coefficients**
- Note that for a system of linear equations to have a unique solution, the matrix of coefficients must be invertible and therefore must be a square matrix
 - In exams, only invertible matrices will be given (except when solving for eigenvectors)
- You should be able to use matrices to solve a system of up to two linear equations both with and without your GDC
- You should be able to use a mixture of matrices and technology to solve a system of up to three linear equations

How do you solve a system of linear equations with matrices?

STEP 1

Write the information in a matrix equation, e.g. for a system of three linear equations $A \begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = B$,

where the entries into matrix $m{A}$ are the coefficients of x , y and z and matrix $m{B}$ is a column matrix

■ STEP 2

Re-write the equation using the inverse of \boldsymbol{A} , $\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \boldsymbol{A}^{-1}\boldsymbol{B}$

■ STFP3

Evaluate the right-hand side to find the values of the unknown variables X, Y and Z

Examiner Tip

• If you are asked to solve a system of linear equations by hand you can check your work afterwards by solving the same question on your GDC

a) Write the system of equations

$$\begin{cases} x + 3y - z = -3 \\ 2x + 2y + z = 2 \\ 3x - y + 2z = 1 \end{cases}$$

in matrix form.

$$\begin{pmatrix} i & 3 & -i \\ 2 & 2 & i \\ 3 & -i & 2 \end{pmatrix} \begin{pmatrix} \infty \\ y \\ z \end{pmatrix} = \begin{pmatrix} -3 \\ 2 \\ i \end{pmatrix}$$

b) Hence solve the simultaneous linear equations.

Re-write the equation in part a) using the inverse matrix

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} \frac{1}{2} & -\frac{1}{2} & \frac{1}{2} \\ -\frac{1}{10} & \frac{1}{2} & -\frac{3}{10} \\ -\frac{6}{5} & 1 & -\frac{2}{5} \end{pmatrix} \begin{pmatrix} -3 \\ 2 \\ 1 \end{pmatrix}$$

Use your GDC to find A-1

if it is larger than a 2x2 matrix

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} -2 \\ 1 \\ 4 \end{pmatrix}$$

$$x = -2$$

$$y = 1$$

$$z = 4$$

Your notes
