Random & Systematic Errors

Random & Systematic Errors

- Measurements of quantities are made with the aim of finding the true value of that quantity
 - In reality, it is impossible to obtain the true value of any quantity as there will always be a degree of uncertainty
- The uncertainty is an estimate of the difference between a **measurement reading** and the **true value**
- The two types of **measurement errors** that lead to uncertainty are:
 - Random errors
 - Systematic errors

Random Errors

- Random errors cause unpredictable fluctuations in an instrument's readings as a result of uncontrollable factors, such as environmental conditions
- This affects the precision of the measurements taken, causing a wider spread of results about the mean value
- To **reduce** random error:
 - **Repeat** measurements several times and calculate an average from them

Reading Errors

- When measuring a quantity using an **analogue** device such as a ruler, the uncertainty in that measured quantity is **±0.5 the smallest measuring interval**
- When measuring a quantity using a **digital** device such as a digital scale or stopwatch, the uncertainty in that measured quantity is **±1 the smallest measuring interval**
- To **reduce** reading errors:
 - Use a more precise device with smaller measuring intervals and therefore less uncertainty

Your notes

Both rulers measure the same candy cane, yet Ruler B is more precise than Ruler A due to a smaller interval size

Systematic Errors

- Systematic errors arise from the use of faulty instruments or from flaws in the experimental method
- This type of error is repeated consistently every time the instrument is used or the method is followed, which affects the accuracy of all readings obtained
- To **reduce** systematic errors:
 - Instruments should be **recalibrated**, or different instruments should be used
 - Corrections or adjustments should be made to the technique

Systematic errors on graphs are shown by the offset of the line from the origin

Page 3 of 21

Zero Errors

- This is a type of systematic error which occurs when an instrument gives a reading when the true reading is zero
 - For example, a top-ban balance that starts at 2 g instead of 0 g
- To account for zero errors
 - Take the difference of the offset from each value
 - For example, if a scale starts at 2 g instead of 0 g, a measurement of 50 g would actually be 50 2
 = 48 g
 - The offset could be positive or negative

Precision

- Precise measurements are ones in which there is very little spread about the mean value, in other words, how close the measured values are to each other
- If a measurement is repeated several times, it can be described as precise when the values are very similar to, or the same as, each other
 - Another way to describe this concept is if the **random uncertainty** of a measurement is **small**, then that measurement can be said to be **precise**
- The precision of a measurement is reflected in the values recorded measurements to a greater number of decimal places are said to be more **precise** than those to a whole number

Accuracy

- A measurement is considered **accurate** if it is close to the true value
 - Another way to describe this concept is if the systematic error of a measurement is small, then that measurement can be said to be accurate
- The accuracy can be increased by repeating measurements and finding a mean of the results
- Repeating measurements also helps to identify anomalies that can be omitted from the final results

- When thinking about the validity of an experiment, a **good question** to ask is
 - How relevant is this experiment to my original research question?

Calculating Uncertainties

Calculating Uncertainties

- There is always a degree of uncertainty when measurements are taken; the uncertainty can be thought of as the difference between the **actual** reading taken (caused by the equipment or techniques used) and the **true value**
- Uncertainties are **not** the same as errors
 - Errors can be thought of as issues with equipment or methodology that cause a reading to be different from the true value
 - The uncertainty is a range of values around a measurement within which the true value is expected to lie, and is an **estimate**
- For example, if the true value of the mass of a box is 950 g, but a systematic error with a balance gives an actual reading of 952 g, the uncertainty is ±2 g
- These uncertainties can be represented in a number of ways:
 - Absolute Uncertainty: where uncertainty is given as a fixed quantity
 - Fractional Uncertainty: where uncertainty is given as a fraction of the measurement
 - Percentage Uncertainty: where uncertainty is given as a percentage of the measurement

percentage uncertainty = $\frac{\text{uncertainty}}{\text{measured value}} \times 100\%$

- To find uncertainties in different situations:
 - The uncertainty in a reading: ± half the smallest division
 - The uncertainty in a measurement: at least ±1 smallest division
 - **The uncertainty in repeated data:** half the range i.e. $\pm \frac{1}{2}$ (largest smallest value)
 - The uncertainty in digital readings: ± the last significant digit unless otherwise quoted

uncertainty in *x*

• The uncertainty in the natural log of a value: absolute uncertainty in ln(x) = "

X

Your notes

READING (I) = 1.6 mA

ABSOLUTE UNCERTAINTY (ΔI) = $\frac{1}{2} \times 0.2 \text{ mA} = 0.1 \text{ mA}$ I = 1.6 ± 0.1 mA

FRACTIONAL UNCERTAINTY =
$$\frac{\text{UNCERTAINTY}}{\text{VALUE}} = \frac{0.1}{1.6} = \frac{1}{16}$$

I = 1.6 ± $\frac{1}{16}$ mA

PERCENTAGE UNCERTAINTY (%) =
$$\frac{\text{UNCERTAINTY}}{\text{VALUE}} \times 100 = \frac{0.1}{1.6} \times 100 = 6.2\%$$

I = 1.6 ± 6.2% mA

How to calculate absolute, fractional and percentage uncertainty

• Always make sure your absolute or percentage uncertainty is to the same number of **significant figures** as the reading

Combining Uncertainties

• When combining uncertainties, the rules are as follows:

Page 8 of 21

Save My Exams

Head to <u>www.savemyexams.com</u> for more awesome resources

Operation	Example	Propagation Rule			
Addition & Subtraction	$y = a \pm b$	$\Delta y = \Delta a + \Delta b$ The sum of the absolute uncertainties			
Multiplication & Division	$y = a \times b \text{ or}$ $y = \frac{a}{b}$	$\frac{\Delta y}{y} = \frac{\Delta a}{a} + \frac{\Delta b}{b}$ The sum of the fractional uncertainties			
Power	$y = a^{\pm n}$	$\frac{\Delta y}{y} = n \left(\frac{\Delta a}{a}\right)$ The magnitude of n times the fractional uncertainty			

Your notes

Adding / Subtracting Data

• Add together the absolute uncertainties

ADDING / SUBTRACTING DATA

Multiplying / Dividing Data

• Add the percentage or fractional uncertainties

Raising to a Power

Multiply the percentage uncertainty by the power

Percentage uncertainties have no units

Remember:

• The uncertainty in constants, such as π, is taken to be zero

Uncertainties in trigonometric and logarithmic functions will not be tested in the exam, so just remember these rules and you'll be fine!

Page 12 of 21

Determining Uncertainties from Graphs

Determining Uncertainties from Graphs

- The uncertainty in a measurement can be shown on a graph as an **error bar**
- This bar is drawn above and below the point (or from side to side) and shows the **uncertainty** in that measurement
- Error bars are plotted on graphs to show the **absolute uncertainty** of values plotted

Representing error bars on a graph

- To calculate the **uncertainty in a gradient**, two lines of best fit should be drawn on the graph:
 - The 'best' line of best fit, which passes as **close** to the points **as possible**
 - The 'worst' line of best fit, either the **steepest possible** or the **shallowest possible** line which fits within all the error bars

Page 13 of 21

Your notes

• The percentage uncertainty in the **y-intercept** can be found using:

Page 14 of 21

🗲 Save My Exams

Head to www.savemyexams.com for more awesome resources

$$percentage uncertainty = \frac{best \ y \ intercept - worst \ y \ intercept}{best \ y \ intercept} \times 100\%$$

$$percentage uncertainty = \frac{max. \ y \ intercept - min. \ y \ intercept}{2} \times 100\%$$
Percentage Difference
$$The \ percentage \ difference \ gives \ an \ indication \ of \ how \ close \ the \ experimental \ value \ achieved \ from \ an \ experiment \ is \ to \ the \ accepted \ value \ it \ is \ not \ a \ percentage \ uncertainty = \frac{experimental \ value - accepted \ value \ x \ 100\%$$

- The experimental value is sometimes referred to as the 'measured' value
- The accepted value is sometimes referred to as the 'true' value

The

The

- This may be labelled on a component such as the capacitance of a capacitor or the resistance of a resistor
- Or, from a reputable source such as a peer-reviewed data booklet
- For example, the acceleration due to gravity g is known to be 9.81 m s⁻². This is its accepted value
 - From an experiment, the value of g may be found to be 10.35 m s⁻²
 - Its percentage difference would therefore be 5.5 %
- The smaller the percentage difference, the more accurate the results of the experiment

Worked example

On the axes provided, plot the graph for the following data and draw error bars and lines of best and worst fit.

Force / N	10	20	30	40	50	60	70	80
Extension / mm	8.5±1	11±0.5	15 ± 1	15 ± 2	20 ± 1.5	19.5 ± 2	22 ± 0.5	26±1

Find the percentage uncertainty in the gradient from your graph.

Answer:

Step 1: Draw sensible scales on the axes and plot the data
