- ★ 3.5.3 Modelling with Trigonometric Functions

3.5.1 Graphs of Trigonometric Functions

Graphs of Trigonometric Functions

What are the graphs of trigonometric functions?

- The trigonometric functions sin, cos and tan all have special periodic graphs
- You'll need to know their properties and how to sketch them for a given domain in either degrees or radians
- Sketching the trigonometric graphs can help to
 - Solve trigonometric equations and find all solutions
 - Understand transformations of trigonometric functions

What are the properties of the graphs of sin x and cos x?

- The graphs of sin x and cos x are both **periodic**
 - They **repeat every 360°** (2π radians)
 - The angle will always be on the x-axis
 - Either in degrees or radians
- The graphs of sin x and cos x are always in the **range -1 ≤ y ≤ 1**
 - Domain: $\{x \mid x \in \mathbb{R}\}$
 - Range: $\{ y \mid -1 \leq y \leq 1 \}$
 - The graphs of sin x and cos x are identical however one is a **translation** of the other
 - sin x passes through the origin
 - cos x passes through (0, 1)
- The **amplitude** of the graphs of sin x and cos x is 1

What are the properties of the graph of tan x?

- The graph of tan x is **periodic**
 - It repeats every 180° (π radians)
 - The angle will always be on the x-axis
 Either in degrees or radians
- The graph of tan x is **undefined** at the points ± 90°, ± 270° etc
 - There are **asymptotes** at these points on the graph

In radians this is at the points
$$\pm \frac{\pi}{2}$$
, $\pm \frac{3\pi}{2}$ etc

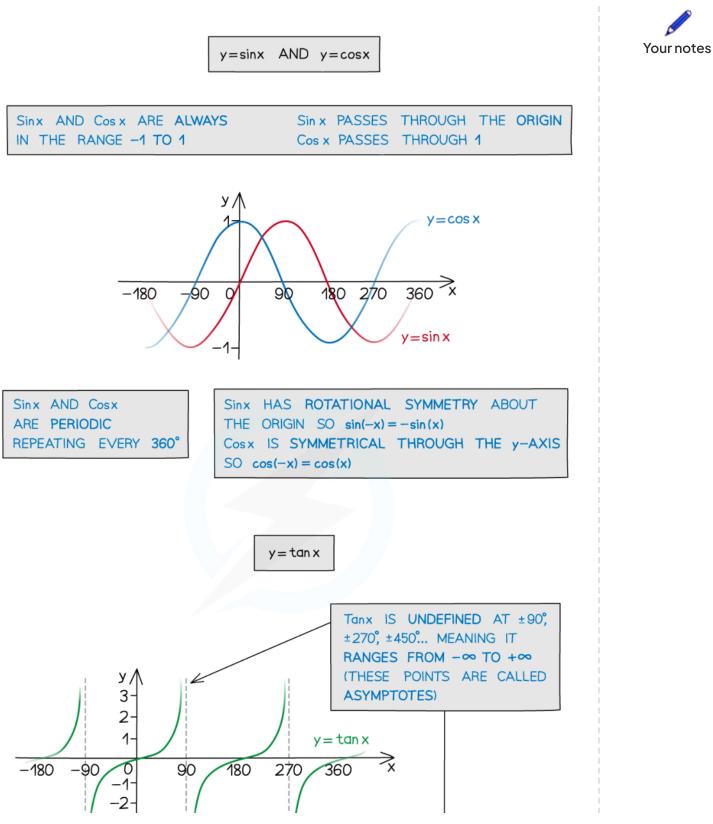

- The range of the graph of tan x is
 - Domain: $\left\{ \boldsymbol{x} \mid \boldsymbol{x} \neq \frac{\boldsymbol{\pi}}{2} + \boldsymbol{k}\boldsymbol{\pi}, \ \boldsymbol{k} \in \mathbb{Z} \right\}$
 - Range: $\{ \boldsymbol{y} \mid \boldsymbol{y} \in \mathbb{R} \}$

• Try to keep the symmetry and rotational symmetry as you sketch, as this will help when using the graph to find solutions

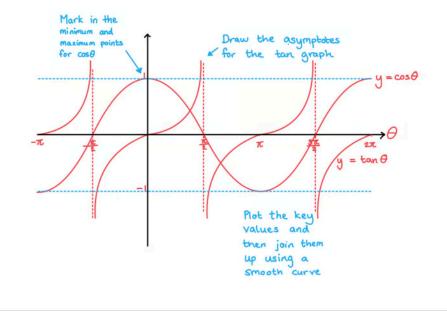

😧 Examiner Tip

Sketch all three trig graphs on your exam paper so you can refer to them as many times as you
need to!

Worked example

Sketch the graphs of $y = \cos\theta$ and $y = \tan\theta$ on the same set of axes in the interval $-\pi \le \theta \le 2\pi$. Clearly mark the key features of both graphs.

Using Trigonometric Graphs

How can I use a trigonometric graph to find extra solutions?

- Your calculator will only give you the first solution to a problem such as sin⁻¹(0.5)
 - This solution is called the **primary value**
- However, due to the **periodic** nature of the trig functions there could be an infinite number of solutions
 - Further solutions are called the **secondary values**
- This is why you will be given a **domain** (interval) in which your solutions should be found
 - This could either be in degrees or in radians
 - If you see π or some multiple of π then you must work in radians
- The following steps will help you use the **trigonometric graphs** to find **secondary values**
 - STEP 1: Sketch the graph for the given function and interval
 - Check whether you should be working in degrees or radians and label the axes with the key values
 - STEP 2: Draw a horizontal line going through the y-axis at the point you are trying to find the values for
 - For example if you are looking for the solutions to sin⁻¹(-0.5) then draw the horizontal line going through the y-axis at -0.5
 - The number of times this line cuts the graph is the number of solutions within the given interval
 - STEP 3: Find the primary value and mark it on the graph
 - This will either be an exact value and you should know it
 - Or you will be able to use your calculator to find it
 - STEP 4: Use the symmetry of the graph to find all the solutions in the interval by adding or subtracting from the key values on the graph

What patterns can be seen from the graphs of trigonometric functions?

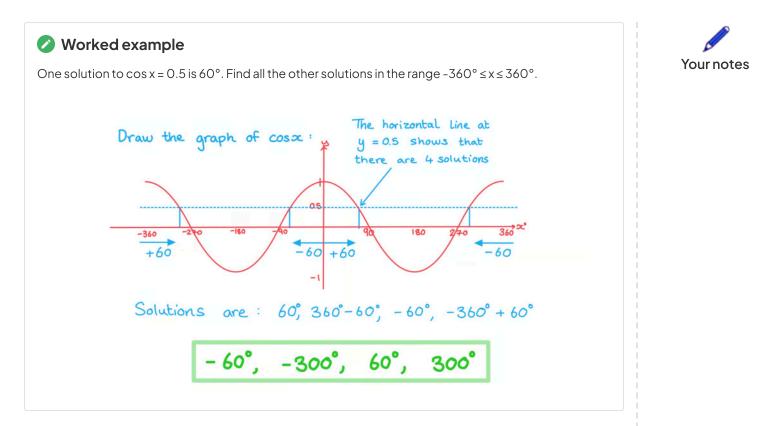

- The graph of sin x has rotational symmetry about the origin
 - So sin(-x) = sin(x)
 - $sin(x) = sin(180^{\circ} x) \text{ or } sin(\pi x)$
- The graph of cos x has reflectional symmetry about the y-axis
 - Socos(-x) = cos(x)
 - cos(x) = cos(360° x) or cos(2π x)
- The graph of tan x repeats every 180° (π radians)
 - So $tan(x) = tan(x \pm 180^\circ) or tan(x \pm \pi)$
- The graphs of sin x and cos x repeat every 360° (2π radians)
 - So $sin(x) = sin(x \pm 360^\circ)$ or $sin(x \pm 2\pi)$
 - $\cos(x) = \cos(x \pm 360^{\circ}) \operatorname{or} \cos(x \pm 2\pi)$

😧 Examiner Tip

• Take care to always check what the interval for the angle is that the question is focused on

3.5.2 Transformations of Trigonometric Functions

Transformations of Trigonometric Functions

What transformations of trigonometric functions do I need to know?

- As with other graphs of functions, trigonometric graphs can be transformed through **translations**, **stretches** and **reflections**
- Translations can be either horizontal (parallel to the x-axis) or vertical (parallel to the y-axis)
 - For the function **y** = **sin** (**x**)
 - A vertical translation of a units in the positive direction (up) is denoted by
 y = sin (x) + a
 - A vertical translation of a units in the negative direction (down) is denoted by
 y = sin (x) a
 - A horizontal translation in the positive direction (right) is denoted by y = sin (x a)
- A horizontal translation in the negative direction (left) is denoted by y = sin (x + a)
- Stretches can be either horizontal (parallel to the x-axis) or vertical (parallel to the y-axis)
 - For the function **y** = **sin** (**x**)
 - A vertical stretch of a factor a units is denoted by y = a sin (x)
 - A horizontal stretch of a factor a units is denoted by $y = sin(\frac{x}{2})$
- **Reflections** can be either across the x-axis or across the y-axis
 - For the function y = sin (x)
 - A reflection across the x-axis is denoted by y = sin (x)
 - A **reflection** across the y-axis is denoted by **y** = **sin** (-**x**)

What combined transformations are there?

- Stretches in the horizontal and vertical direction are often combined
- The functions **a** sin(bx) and **a** cos(bx) have the following properties:
 - The **amplitude** of the graph is |a|

.

The **period** of the graph is
$$\frac{360}{b}$$
 ° (or $\frac{2\pi}{b}$ rad)

- Translations in both directions could also be combined with the stretches
- The functions a sin(b(x c)) + d and a cos(b(x c)) + d have the following properties:
 - The **amplitude** of the graph is |a|

The **period** of the graph is
$$\frac{360}{b}$$
 ° (or $\frac{2\pi}{b}$)

- The translation in the horizontal direction is c
- The translation in the vertical direction is d
 - d represents the **principal axis** (the line that the function fluctuates about)
- The function a tan(b(x c)) + d has the following properties:
 - The **amplitude** of the graph does not exist

Page 8 of 15

SaveMyExams

$$\frac{180}{2\pi}$$

- The **period** of the graph is b° (or b°
- The translation in the horizontal direction is c
- The translation in the vertical direction (principal axis) is d

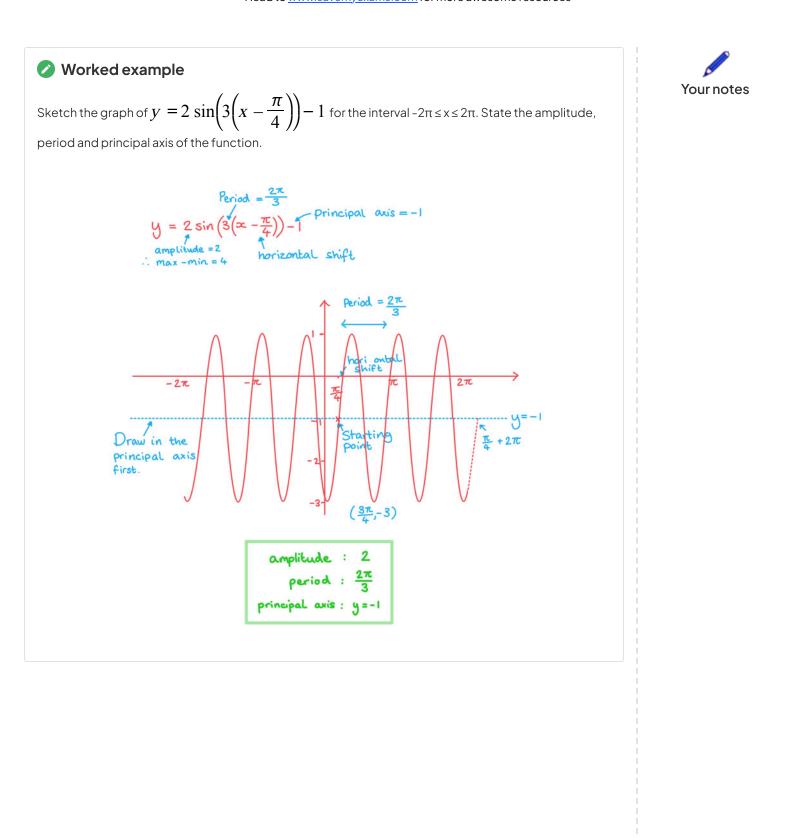

How do I sketch transformations of trigonometric functions?

- Sketch the graph of the original function first
- Carry out each transformation separately
 - The **order** in which you carry out the transformations is important
 - Given the form y = a sin(b(x c)) + d carry out any stretches first, translations next and reflections last
 - If the function is written in the form y = a sin(bx bc) + d factorise out the coefficient of x before carrying out any transformations
 - Use a very light pencil to mark where the graph has moved for each transformation
- It is a good idea to mark in the principal axis the lines corresponding to the maximum and minimum points first
 - The **principal axis** will be the line **y** = **d**
 - The **maximum points** will be on the line **y** = **d** + **a**
 - The **minimum points** will be on the line **y** = **d a**
- Sketch in the new transformed graph
- Check it is correct by looking at some key points from the **exact values**

😧 Examiner Tip

- Be sure to apply transformations in the correct order applying them in the wrong order can produce an incorrect transformation
- When you sketch a transformed graph, indicate the new coordinates of any points that are marked on the original graph
- Try to indicate the coordinates of points where the transformed graph intersects the coordinate axes (although if you don't have the equation of the original function this may not be possible)
- If the graph has asymptotes, don't forget to sketch the asymptotes of the transformed graph as well

3.5.3 Modelling with Trigonometric Functions

Modelling with Trigonometric Functions

What can be modelled with trigonometric functions?

- Anything that oscillates (fluctuates periodically) can be modelled using a trigonometric function
 - Normally some transformation of the sine or cosine function
- Examples include:
 - D(t) is the depth of water at a shore t hours after midnight
 - T(d) is the temperature of a city d days after the 1st January
 - H(t) is vertical height above ground of a person t seconds after entering a Ferris wheel
- Notice that the x-axis will not always contain an angle
 - In the examples above time or number of days would be on the x-axis
 - Depth of the water, temperature or vertical height would be on the y-axis

What are the parameters of trigonometric models?

- A trigonometric model could be of the form
 - $f(x) = a \sin(b(x-c)) + d$
 - $f(x) = a \cos(b(x c)) + d$
 - $f(x) = a \tan(b(x c)) + d$
- The *a* represents the **amplitude** of the function
 - The bigger the value of a the bigger the range of values of the function
 - For the function $a \tan(b(x-c)) + d$ the amplitude is undefined
- The b determines the **period** of the function

Period =
$$\frac{360^{\circ}}{h} = \frac{2\pi}{h}$$

- The bigger the value of b the quicker the function repeats a cycle
- The c represents the horizontal shift
- The d represents the vertical shift
 - This is the **principal axis**

What are possible limitations of a trigonometric model?

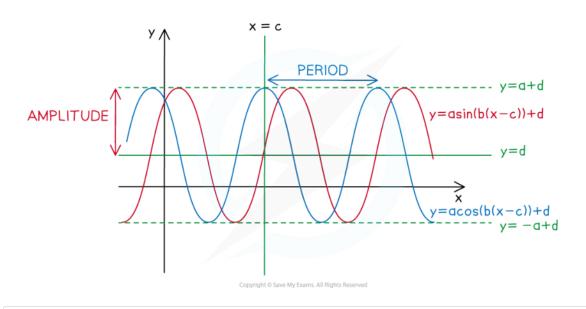

- The amplitude is the same for each cycle
 - In real-life this might not be the case
 - The function might get closer to the value of d over time
- The period is the same for each cycle
 - In real-life this might not be the case
 - The time to complete a cycle might change over time

Your notes

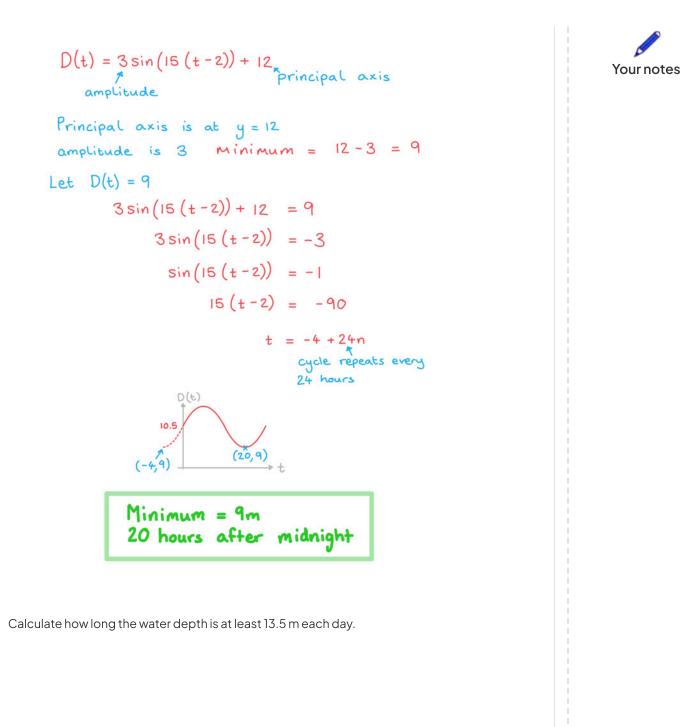

Examiner Tip

- The variable in these questions is often **t** for time.
- Read the question carefully to make sure you know what you are being asked to solve.

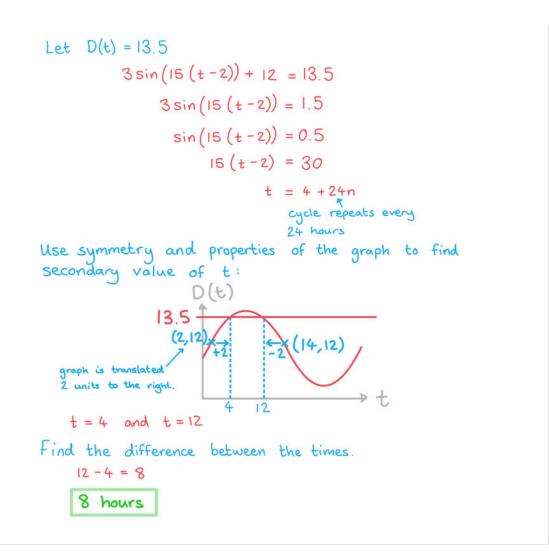

Worked example

C)
