5.6.1 Kinematics Toolkit

Displacement, Velocity & Acceleration

What is kinematics?

- Kinematics is the branch of mathematics that models and analyses the motion of objects
- Common words such as **distance**, **speed** and **acceleration** are used in kinematics but are used according to their technical definition

What definitions do I need to be aware of?

- Firstly, only motion of an object in a straight line is considered
 - this could be a **horizontal** straight line
 - the **positive** direction would be to the **right**
 - or this could be a **vertical** straight line
 - the **positive** direction would be **upwards**

Particle

- A particle is the general term for an object
 - some questions may use a **specific** object such as a **car** or a **ball**

Time t seconds

- Displacement, velocity and acceleration are all functions of time t
- Initially time is zero t = 0

Displacement S m

- The displacement of a particle is its distance relative to a fixed point
 the fixed point is often (but not always) the particle's initial position
- **Displacement** will be zero s = 0 if the object is at or has returned to its initial position
- **Displacement** will be negative if its **position relative** to the **fixed point** is in the **negative direction** (left or down)

Distance d m

- Use of the word **distance** needs to be considered carefully and could refer to
 - the distance travelled by a particle
 - the (straight line) distance the particle is from a particular point
- Be careful not to confuse **displacement** with **distance**
 - if a bus route starts and ends at a bus depot, when the bus has returned to the depot, its
 displacement will be zero but the distance the bus has travelled will be the length of the route
- Distance is always positive

Velocity Vms⁻¹

• The velocity of a particle is the rate of change of its displacement at time t

Page 2 of 12

SaveMyExams

- Velocity will be negative if the particle is moving in the negative direction
- A velocity of zero means the particle is stationary V = 0

Speed $|V| \text{ m s}^{-1}$

- **Speed** is the **magnitude** (a.k.a. absolute value or modulus) of **velocity**
 - as the particle is **moving** in a **straight line**, **speed** is the **velocity ignoring** the **direction**

• if
$$V = 4$$
, $|V| = 4$

• if
$$v = -6$$
, $|v| = 6$

Acceleration a m s⁻²

- The acceleration of a particle is the rate of change of its velocity at time t
- Acceleration can be **negative** but this alone cannot fully describe the particle's motion
 - if velocity and acceleration have the same sign the particle is accelerating (speeding up)
 - if velocity and acceleration have different signs then the particle is decelerating (slowing down)
 - if acceleration is zero a = 0 the particle is moving with constant velocity
 - in all cases the **direction** of **motion** is determined by the **sign** of **velocity**

Are there any other words or phrases in kinematics I should know?

- Certain words and phrases can imply values or directions in kinematics
 - a particle described as "at **rest**" means that its velocity is zero, v = 0
 - a particle described as moving "due east" or "right" or would be moving in the positive horizontal direction
 - this also means that v > 0
 - a particle "dropped from the top of a cliff" or "down" would be moving in the negative vertical direction
 - this also means that v < 0

What are the key features of a velocity-time graph?

- The gradient of the graph equals the acceleration of an object
- A straight line shows that the object is accelerating at a constant rate
- A horizontal line shows that the object is moving at a constant velocity
- The area between graph and the x-axis tells us the change in displacement of the object
 - Graph **above** the x-axis means the object is moving **forwards**
 - Graph **below** the x-axis means the object is moving **backwards**
- The total displacement of the object from its starting point is the sum of the areas above the x-axis minus the sum of the areas below the x-axis
- The total distance travelled by the object is the sum of all the areas
- If the graph touches the x-axis then the object is stationary at that time
- If the graph is **above** the **x-axis** then the object has positive velocity and is **travelling forwards**
- If the graph is **below** the **x-axis** then the object has negative velocity and is **travelling backwards**

Worked example

A particle is projected vertically upwards from ground level, taking 8 seconds to return to the ground.

The velocity-time graph below illustrates the motion of the particle for these 8 seconds.

- i) How many seconds does the particle take to reach its maximum height? Give a reason for your answer.
- ii) State, with a reason, whether the particle is accelerating or decelerating at time t = 3.

i. At maximum height, velocity is zero v=0 at t=4

> *The particle takes & seconds to reach its maximum height. This is because its velocity is 0 m s⁻¹ at & seconds.

- ii. At E=3, velocity is POSITIVE Acceleration is the gradient of velocity At E=3, acceleration is NEGATIVE
 - At 3 seconds the particle is decelerating as its velocity and acceleration have different signs.

5.6.2 Calculus for Kinematics

Differentiation for Kinematics

How is differentiation used in kinematics?

- Displacement, velocity and acceleration are related by calculus
- In terms of differentiation and derivatives

velocity is the rate of change of displacement

$$v = \frac{\mathrm{d}s}{\mathrm{d}t} \text{ or } v(t) = s'(t)$$

• acceleration is the rate of change of velocity

•
$$a = \frac{\mathrm{d}v}{\mathrm{d}t}$$
 or $a(t) = v'(t)$

• so acceleration is also the second derivative of displacement

•
$$a = \frac{\mathrm{d}^2 s}{\mathrm{d}t^2}$$
 or $a(t) = s''(t)$

- If a graph is not given you can use your GDC to draw one
 - you can then use your GDC's graphing features to find **gradients**
 - velocity is the gradient on a displacement (-time) graph
 - acceleration is the gradient on a velocity (-time) graph

Worked example

The displacement, s m, of a particle at t seconds, is modelled by $s(t) = 2t^3 - 27t^2 + 84t$

- i. Find v(t) and a(t).
- ii. Find the times at which the particle is at rest.

i.
$$v(t) = s'(t) = 6t^2 - 5t + 8t + 8t + 6(t^2 - 9t + 14t)$$

 $a(t) = v'(t) = 12t - 5t = 6(2t - 9)$
 $\therefore v(t) = 6(t - 7)(t - 2)$
 $a(t) = 6(2t - 9)$
ii. The particle is at rest when $v(t) = 0$
 $6(t - 7)(t - 2) = 0$
 $t = 7, t = 2$
 \therefore The particle is at rest at
2 seconds and 7 seconds

Integration for Kinematics

How is integration used in kinematics?

- Since **velocity** is the **derivative** of **displacement** ($V = \frac{ds}{dt}$) it follows that
 - $s = \int v \, \mathrm{d}t$
- Similarly, velocity will be an antiderivative of acceleration

$$v = \int a \, \mathrm{d}t$$

How would I find the constant of integration in kinematics problems?

- A **boundary** or **initial** condition would need to be known
 - phrases involving the word "initial", or "initially" are referring to time being zero, i.e. t=0
 - you might also be given information about the object at some other time (this is called a **boundary** condition)
 - substituting the values in from the initial or boundary condition would allow the constant of integration to be found

How are definite integrals used in kinematics?

- Definite integrals can be used to find the displacement of a particle between two points in time
 - $\int_{t_1}^{t_2} v(t) dt$ would give the **displacement** of the particle **between** the times $t = t_1$ and $t = t_2$
 - This can be found using a velocity-time graph by **subtracting** the **total area below** the horizontal axis from the **total area above**
 - $\int_{t_1}^{t_2} |v(t)| dt$ gives the **distance** a particle has **travelled** between the times $t = t_1$ and $t = t_2$
 - This can be found using a velocity velocity-time graph by **adding** the **total area below** the horizontal axis to the **total area above**
 - Use a GDC to plot the modulus graph y = |v(t)|

Your notes

O Examiner Tip

 Sketching the velocity-time graph can help you visualise the distances travelled using areas between the graph and the horizontal axis

Worked example

A particle moving in a straight horizontal line has velocity (V m s⁻¹) at time t seconds modelled by $v(t) = 8t^3 - 12t^2 - 2t$.

i. Given that the initial position of the particle is at the origin, find an expression for its displacement from the origin at time t seconds.

ii. Find the displacement of the particle from the origin in the first five seconds of its motion.

iii. Find the distance travelled by the particle in the first five seconds of its motion.
